May 2007

Abstract

This paper examines the performance of minimum wage legislation in Kenya, both in terms of its coverage and enforcement as well as in terms of their associations with wages and employment. Our findings based on the 1998/99 labor force data—the last labor force survey available-- indicate that minimum wages were better enforced and had stronger effects in the urban areas than in the agriculture industry. More specifically, our results suggest that (i) compliance rates were higher in urban areas, (ii) minimum wages are positively associated with wages of unskilled workers and women in urban areas, while no such relationship is found for workers in agriculture, and (iii) higher minimum wages were associated with a lower share of workers in formal activities in a given occupation and location. Our estimates indicate that a 10 percent point increase in the minimum to median wage ratio could be associated with a decline in the share of formal employment of between 1.2-5.6 percentage points –and an increase of between 2.7-5.9 points in the share of self-employment.

¹ This paper has been prepared as background work for the World Bank study “Jobs in Kenya”. The authors are deeply indebted to Sara Lemos, Sumana Dhar and the Government of Kenya for very valuable comments and discussions.

I. Introduction

Policies to set “living wages” are a popular but contentious instrument. As Blanchard (2002) suggests, the main reason for instituting minimum wages is to empower workers whose wages are constrained by the excessive market power of employers. To the extent that minimum wages are enforced they can bring sizeable income gains to a number of workers leading to reductions in poverty and inequality at relatively small costs in terms of employment. However, much of the existing evidence for developing countries indicates that minimum wages bring undesirable side effects, displacing workers from formal sector jobs. The effectiveness of this instrument in lower income countries has also been questioned on the grounds that it tends to cover a small minority of relatively well-off workers in the formal sector, leaving the vast majority of informal workers behind. At the same time however, the evidence is far from conclusive. The fact that different effects are found across different countries underscores the importance of country-specific factors --such as the level at which minimum wages are set or the structure of the labor market-- to determine its effects.

As many other countries, Kenya has held an active minimum wage setting policy since independence. There are as many as seventeen minimum wage orders, setting a large number of minimum wage floors that vary by occupation, sector of activity and location. Many of such minimum wages are updated annually.

Evidence of the effect of minimum wages in African countries, including Kenya, is hampered by the scarcity of data. In a descriptive paper, Omolo and Omitti (2004) find that the minimum wage policy in Kenya has failed to contribute to sustained poverty reduction. Moreover, using aggregate time series data they find a negative correlation between minimum wages and modern private sector employment. This paper contributes to the literature of the effects of minimum wages on the Kenyan labor market by: (i) examining the performance of the legislation of minimum wages in Kenya, both in terms of its coverage and enforcement, and (ii) estimating the effects on wages and employment using micro data. Our findings based on the 1998/99 labor force data indicate that

minimum wages were better enforced and had stronger effects in the urban areas than in agriculture industry. More specifically, our results suggest that (i) compliance rates were higher in urban areas, (ii) minimum wages raised wages for unskilled workers and women in urban areas, while no such effects were found for workers in agriculture, and (iii) higher minimum wages were associated with a lower share of workers in formal activities, and a higher share of workers in self-employment in a given occupation and location.

The rest of the paper is organized as follows: Section two lays down the arguments and empirical evidence for and against minimum wage setting. Section three describes the institutions for minimum wage setting in Kenya. Section four presents the data used in this study. Section five examines the enforcement and wage effects of minimum wages. Section six reports some estimates of its effects on the structure of employment and section seven concludes.

II. Arguments For and Against Minimum Wages

The main justification for instituting minimum wages is to empower workers whose wages are constrained by the excessive market power of employers (Blanchard, 2002). This situation is likely to emerge in markets where there are very few employers or workers do not have the information or the income to search for better paying jobs. The most extreme cases are mining enclaves or one-company towns, where workers have the choice of accepting a very low wage or not working at all. Lack of job registries and unemployment insurance also reduce the bargaining power of workers by limiting their capacity to search for alternative jobs.

Another two arguments proposed in favor of minimum wage setting relate to efficiency-wage arguments and the fact that minimum wages increase workers' purchasing power, which in turn can stimulate labor demand (Levin-Waldman, 1997). The efficiency-wage argument states that higher wages can increase workers' productivity, which in turn allows employers to pay higher wages. One reason for an increase in productivity might

be that higher wages allow workers to improve their nutrition and their human development. Another version of this argument is that minimum wages force managers to provide on-the-job training, which makes workers more productive. Yet, it may be also argued that in the absence of well developed incentives to provide training, firms may just become more selective, hiring workers with higher productivity rather than incurring in the cost of training them. On its part, the purchasing power argument requires that low wage business benefit from the higher consumption of low-income workers, which may not necessarily be the case. In absence of that link the effects are likely to be small, as increased sales are not likely to compensate for higher wage costs.

A central rationale for minimum wage legislation is that it helps lift the working poor out of poverty by raising their wages. Fields and Kanbur (2007) develop a model that allows for income-sharing between employed and unemployed persons in society and within families. Their results indicate that poverty can actually decrease, increase or remain unchanged depending on the degree of poverty aversion, the elasticity of labor demand, the ratio of the minimum wage to the poverty line, and the extent of income sharing.

Yet, despite its potential gains, there are also important reasons to be cautious in the use of minimum wages as a policy instrument. The standard competitive model predicts that forcing the price of labor above the price attained in the market leads to job losses in firms where regulations are enforced, and an increase in employment in the uncovered sector. This model relies on the assumption that workers are paid their marginal value and therefore, any attempts to raise wages above that value, price workers out of jobs. The ultimate effect of minimum wage depends on whether the statutory minim is set above the marginal value of labor, which ultimately is an empirical question.

Most of the empirical literature focuses on the effect of minimum wages on poverty, inequality and employment. A number of studies have documented that minimum wage policies can reduce wage inequality and poverty in developing countries. For example, Lemos (2004) finds a strong effect of the minimum wage in compressing the wage distribution in Brazil, despite a large share of informal employment. For Latin America,

Morley (1995) finds that poverty falls as the minimum wage rises. Lustig and McLeod (1997) use time series data for a number of developing countries to study the effects of minimum wages on poverty and confirm that increases in the minimum wages are associated with declines in short-term poverty. In fact, Maloney and Nuñez (2004) document that in some countries minimum wages can be an important reference wage in the informal sector, thus contributing to alter the distribution of wages also in that sector.

The evidence on the effects on employment is quite mixed. A number of studies in developed countries have failed to find significant negative impacts.² However other studies find sizeable negative effects³. In contrast, most of the evidence for developing countries points to negative employment effects, in particular when wages are set at relatively high levels in relation to the median wage. Bell (1997) uses firm level data for Mexico and Colombia and finds that in the latter a 10% increase in minimum wages leads to a decline in low-wage employment of 2-12% (depending on the specification). Instead, she finds no effects in Mexico where the minimum wage is set at a lower level relative to the median wage. Maloney and Nuñez, (2004) also identify negative effects in Colombia. Cowan et al. (2004) and Montenegro and Pagés (2004) find negative effects of an increase in minimum wages in Chile. Gindling and Terrel (2005) analyze the effect of multiple minimum wages –much like in Kenya—on employment in Costa Rica. They find that a 10 percent increase reduces formal employment by 1 %. Rama (2001) studies the effect of the minimum wage in Indonesia and finds an effect of similar magnitude (2%). In contrast, Lemos (2004) finds little evidence of adverse employment effects in Brazil.

Evidence for Africa is hampered by the scarcity of data. Nonetheless, the existing studies also suggest negative effects on employment. Jones (1997) finds that a 10 percent increase in minimum wages in Ghana leads to a decline in manufacturing employment of

² Card and Krueger (1994) found no evidence that a raise in the minimum wage lead to a decline in firm-level employment in a low wage sector (fast-food) in the United States. Dickens, Machin and Manning (1999) studied the effect of Minimum Wages in Britain using longitudinal data on workers and also found little impact on employment.

³ See for example, Brown, Gilroy and Khon (1982) for young workers, or Neumark, Schweitzer and Wascher (2000).

between 5-6% and an increase in employment in the informal sector. However, some of her estimates point to smaller effects. Borat (2000) finds that mandatory wage increases in South Africa would result in significant job losses in low pay occupations, such as low-paid domestic workers and farm workers. Finally, Omolo and Omitti (2004) find similar negative effects in Kenya. All in all, the available evidence points to negative and in some cases sizeable effects of minimum wages on employment.

III. Institutions for Minimum Wage Setting

Minimum wages in Kenya are specified as part of a national wage policy set in place before independence and guided by the Regulation of Wages and Conditions of Employment Act (CAP 229). The objective of such policy has been to reduce poverty as well as to protect and promote the living standards of workers (Omolo and Omitti, 2004)

Two wage boards: The Agricultural Wages Advisory Board (AWAB) and the General Wages Advisory Board (GWAB) give recommendations on the wages that might be published each year on May 1 and the employment conditions of workers. The GWAB has the authority to appoint Wage Councils to set statutory working conditions and minimum wages in different occupations. There are 17 such wage councils, but most of them have only updated statutory wages on an ad-hoc basis and so they are often outdated. The AWAB and the GWAB set statutory minimum wage orders for agricultural workers and for workers who are not covered by specific-wage boards, respectively. The boards have a tripartite structure (dominated by the Ministry of Labor, the central organization of trade unions and the Federation of Kenyan Employers) and are chaired by an independent member (usually a labor market or industry expert). Given the advisory status of the boards, the Ministry of Labor can modify their proposals without consultation. Since 2002, the government has not specified the statutory minimum wages for labor below 18 years of age in order to discourage the employment of children.

Within agriculture or the general order, statutory minimum wages vary by age and occupation. In addition, for the general order, minimum wages also vary by location, distinguishing three separate urban areas with different minimum wage levels. These geographical areas are: Nairobi and Mombassa, other municipalities, and other towns.

The classification of occupations retains the colonial job classification in Kenya, --with a few additions and no subtractions over time-- implying that some wage categories may be irrelevant for the current job market. Tables 1 and 2 list the schedule of minimum wages specified by the agricultural and general order, respectively, for the years 1997-2004. Within occupation and locations, minimum wages increase with the skill level and with city size. Despite the many values of the minimum wages, relative minimum wages have been kept constant by virtue of multiplying all minimum wages by the same growth factor.⁴ Therefore, different minimum wages across occupations have not contributed to modify relative wages across occupations or locations.

In real terms, minimum wages fell sharply from the period 1991 to 1994 and then increased afterwards at a rate of 2 percent a year. However, in 2004 real wages had not recovered the 1991 level (Figure 1). In the last years (since 1998) real minimum wages have grown in line with real GDP per capita, but much below the growth rate of real wages in the private sector (Figure 1). The evolution of the real minimum wage is almost identical if rather than a price index for the lower income group, available only for Nairobi, an overall CPI index, obtained from the World Development Indicators (WDI) is used.

The stabilization of inflation in 1995 brought real gains in minimum and average wages. However, the relaxation of wage guidelines in mid 1994 was followed by an upward adjustment of real wages in both the public and the private sector (Kulundu Manda, 2002), which was not accompanied by similar adjustments in the minimum wage. In fact, compared to the average wage, minimum wages for general laborers declined from 0.35 of the average wage in the private sector in 1994, to 0.17 in 2004 (Figure 2). Given this evolution it is quite unlikely that minimum wages are behind the sharp increase in average wages experienced since 1994.

⁴ That is, with very few exceptions, the ratio of any minimum wage to the average minimum wage has been constant over the last years.

III. Data

In this study, we rely on aggregate data from the Central Bureau of Statistics (*Economic Survey*, various years) and micro-data from the 1998/99 Integrated Labour Force Survey (ILFS), a nationally representative survey conducted during the months of December 1998 and January 1999 to 11,040 households. At the individual level there are records for 52016 individuals. The main purpose of this survey was to gather information on the labor force, the informal sector and child labor in Kenya.

In the analysis that follows the term “salaried” or “paid employees” refers to all workers working for someone else, in exchange for a wage or a salary. Salary is defined as income from paid employment before adding other benefits and allowances, and before deducting taxes and other compulsory deduction. The self-employed category is comprised of working employers and own account workers, that is, people that operate their own businesses. Working employers hire one or more employees and own account workers hire no employees. Unskilled workers in agricultural activities and general laborers under the regulations of the GWAB are those who work in elementary occupations according to the International Standard Classification of Occupations (ISCO-88).

The informal sector, also referred to as "*Jua Kali*", covers all small-scale activities that are normally semi-organised and unregulated, and use low and simple technology. The formal sector includes the modern sector (private and public) as well as small-scale agriculture and pastoralist activities. Finally, we classify as low educated workers those whose highest education attainment is incomplete secondary or less while educated workers are those who have completed secondary schooling or more.

Panels I and II of Table 3 report summary statistics for the entire population and for those who work. For the latter, we restrict the sample to those between 18 and 65 years old.⁵

⁵ We excluded workers below 18 years because, for this age group, the official publications on minimum wages of the CBS reproduced in Tables 1 and 2 of this document solely report minimum wages for

Data indicates a high share of children (42 percent) and of low educated people (8 percent with primary education or less), and a majority of the people living in rural areas (74 percent) Out of those who live in urban areas 35.7 percent are concentrated in the largest cities: Nairobi and Mombassa.

Regarding those in work, one in four workers were self-employed, 33.6 percent were paid employees and a large majority of employed workers were in unpaid work (43 percent). Out of those in salaried jobs, one quarter were in the informal sector, 55 percent lived in urban areas, 14 percent were engaged in agricultural activities and 30 percent were public sector employees.

Panel III of Table 3 presents wage indicators for salaried workers aged 18-64 who earned positive wages in the month of reference and worked full time. Restricting the sample this way yields 3,331 observations. Not surprisingly, earnings were lower in the informal compared to those in the formal sector. In addition, wage inequality was higher in the informal sector.

IV. Incidence and Compliance of Minimum Wages

Minimum wages in Kenya are said to suffer from inadequate enforcement. Omolo and Omitti (2004) indicate that “[even] the government itself does not adhere to the minimum wage regulations” (p.16). Using microdata from the 1998/99 Integrated Labor Force Survey (ILFS)—the last cross section of household data available— it is possible to estimate the degree of coverage and enforcement of the minimum wage in that year. These calculations are performed separately for general order (urban areas) and agricultural minimum wages.

We determine the specific minimum wage that applies to each worker based on the reported sector of activity, geographical location and the occupation according to the

unskilled, stockman, herdsman and watchman in agricultural activities. Moreover, since 2002, the government no longer specifies the statutory minimum wages for labor below 18 years of age in order to discourage child employment.

Regulation of Wages and Conditions of Employment Act and the (ISCO-88). It is quite difficult to match the list of occupations listed in the Minimum wage schedule with the ISCO-88 classification of occupations. For example, the minimum wage schedule lists at least four different minimum wages for clerical jobs. Thus, it distinguishes between junior clerks, typists, cashiers and general clerks. Given these difficulties, we follow the following methodology to match workers to minimum wage categories: For all workers for whom there is no clear match to the MW categories we assign them to the general laborer minimum wage. This is the wage that according to the minimum wage regulation applies to all workers except when other orders specify a higher minimum wage. For workers for which a match between the ISCO occupation and the MW schedule is done and the MW schedule specifies a higher minimum wage than the wages for general laborers, we replace the general minimum wage with the higher minimum wage specified under the law. Finally, when the MW distinguishes different levels of MW for workers within the same occupation group, we assign the lower minimum wage within category. For example in the case of clerks, this implies that all non-clearly assigned workers in clerical jobs are given the “junior clerk” minimum wage level.

There are several additional sample restrictions. 1,661 of the 3,331 workers who earned positive wages in the month of reference and worked full time were engaged in non-agricultural activities in rural zones. The laws of minimum wages suggest the GWAB should fix minimum wages for workers in rural areas engaged in non-agricultural activities. However, we were unable to find the schedule of minimum wages that apply to these workers in the official publications of the CBS so we had to drop these people from the analysis. The self-employed are not included in these calculations since they are not covered by minimum wage laws. In addition, earnings data for self-employed workers is not available. Unpaid family workers are also excluded. Additional restrictions due to missing data on status of employment reduce the sample to 1772 observations. Non-compliance rates (reported below) would be much higher if this large group was included in the calculations.

We find substantial non-compliance rates. About 24 percent of the salaried workers in agriculture and 17 percent of salaried workers in non-agricultural activities in urban areas earned monthly wages below the statutory minimum (see Table 4, column identified as *Fraction below*). Non-compliance was particularly high among workers in the higher skill occupations in urban zones such as dyers, crawlers, tractor drivers, salesmen, saw doctor or caretakers where it reached 67 percent. Among the different types of workers, non-compliance was similar for men and women in agriculture, but much higher for women (25%), relative to men (7%), in the general order (Table 5). Non-compliance was also higher for less educated workers, particularly in agriculture and for young workers (18-25 years old) both in agricultural and in general order (Tables 6 and 7). Within the general order regime, non-compliance was higher in municipalities other than Nairobi and Mombassa (Table 8).

The ILFS data allows identifying the percentage of workers whose earnings are at the minimum wage level. This percentage is usually identified with the term “Fraction”. Only a small fraction of salaried workers received monthly wages equal to the statutory minimum. If fraction is measured as all workers whose earnings are within a range of plus/minus two percent of the statutory minimum wage, it is found that only 0.3 percent of the workers in agricultural activities, and 2.1 percent of workers in urban areas had earnings within that range (see Table 4, column identified as *fraction at +/-2 %*) Even when this interval is increased to plus/minus 5 percent of the minimum wage, the share of workers whose earnings fall in that range is not very large: 6.8 percent for agricultural and 2.9 for urban workers. The fraction at the minimum wage is higher for men, less educated and young workers.

The number of workers whose wage and employment status are potentially influenced by the minimum wage increases somewhat if we adopt as a measure of the importance of the minimum wage the *fraction affected*, that is the proportion of workers whose wages are just above the 1998 minimum wage, but below the wage set the following year in May 1st, 1999.⁶ These workers could have potentially lost their jobs after the following update

⁶ When reporting fraction affected, wages are expressed in constant prices of October 1997.

if the wage in 1998/99 reflected their productivity. According to this measure, 8.1 percent of the workers in agriculture and 5.1 in general order were at risk of being affected by the minimum wage increase. This percentage is higher for women, less educated and younger workers.

The ratio of the minimum to the average wage is a widely used measure to assess the toughness of the minimum wage. This measure is often called the *Kaitz ratio*. Another often reported measure is the ratio of the minimum wage relative to the median wage in the economy. Measures referred to the median wage are more appropriated in countries with high earnings inequality or in instances where the minimum wage could be affecting the average wage. Based on this latter indicator, minimum wages in Kenya are 0.39 and 0.76 of the median wage for agricultural and general order, respectively (see last column in Tables 4-8) By way of comparison Maloney and Nuñez (2004) find this indicator to be 0.68 in Colombia, a country in which minimum wages are considered to be high and binding. This ratio is lower for the unskilled occupations in both the agricultural and general order. However, a number of minimum wages for semiskilled or skilled occupations are set at levels that are very high relative to the median wages (above 2/3 of the median).

Based on the 1998/9 levels—there were 18 minimum wages that were higher than 70 percent of the median in urban areas (Table 9). By way of comparison, Levin-Waldman, 1997 suggests setting minimum wages at the median of the unskilled labor wages. In Kenya, most minimum wages in urban areas are way above that range. And while minimum wages in rural areas look low, they are still above this threshold when compared to the wages of unskilled labor for agricultural areas (Table 9).

V. Incidence of the Minimum Wage on Wage level and Distribution

The analysis of the coverage, level and incidence of the minimum wage yields a mixed picture. While wages are set at quite high levels relative to the median wage, non-compliance is high and the fraction of workers that receive wages at the minimum is

relatively small. The latter suggest that minimum wages may not be affecting the level or the distribution of wages in a noticeable way.

The Labor Force data (1998/1999) indicates that across occupations there is a strong positive relation between the level and the percentage of non-compliance of the minimum wage, as shown in Figure 3. The former suggests that in Kenya, attempts to raise the minimum wage to significant levels in relation to the median wage lead to increasing non-compliance, thus reducing the scope for effects of the minimum wage on wages.

A common way to judge whether minimum wages have an influence in the overall wage distribution is to assess the shape of the distribution and see whether a large number of workers are bunched around the minimum wage level. If minimum wages do not exert any influence, the distribution of the logarithm of wages will display a typical Normal curve. If instead, the minimum wage is exerting a significant influence, many workers will receive wages at the minimum level and the wage distribution will show a spike at the minimum wage. In addition, there will be few workers with earnings immediately below the statutory minimum, as their wages will have been pushed up by the effect of establishing a wage floor. To accommodate the fact that Kenya has a large number of minimum wages, we present two curves in the same graph. The first presents the distribution of minimum wages; the second is a histogram of the wage distribution. Spikes in the distribution of minimum wages indicate minimum wage levels that, at least in principle, are applicable to many workers. These are the levels of the minimum wage that are likely to exert a higher influence in the distribution of wages, and the ones on which we focus our attention.

Figures 4 and 5 present the distribution of wages and minimum wages in the agricultural sector for formal and informal salaried workers, respectively. We focus first on the distribution of minimum wages. The solid line in the figure indicates how many workers are subjected to each level of minimum wages. The spikes in this curve indicate that in agriculture, two minimum wage levels apply, at least in principle, to a large number of workers. These are the statutory wages for unskilled workers and for stockman,

herdsman and watchman. In comparison, minimum wages for other occupations are applicable only to a small number of salaried agricultural workers. We then assess whether the distribution of wages displays spikes at any of the two minimum wage levels mentioned above, either in the formal or informal wage distribution. This would indicate that statutory minimum wages alter the wage distribution. An examination of Figures 4 and 5 shows that there are no spikes in the wage distribution at the two mentioned minimum wage levels in the formal or in the informal sector, even though compliance levels are higher in the formal sector

In contrast, general order minimum wages do appear to affect the distribution of wages in urban areas. An inspection to Figure 6 suggests a large spike at the second lowest general order minimum wage (general laborers in municipalities other than Nairobi and Mombassa), which is not evident in the figure for informal employment (Figure 7). Figure 6 also reveals substantial compliance with the minimum wage. The distribution of wages for formal workers lies mostly at the right of the minimum wage for general laborers. Instead, non-compliance is high and minimum wages appear not to affect the distribution of wages in the informal sector (Figure 7).

The former finding suggests that minimum wages might be pushing up the level of wages for formal workers in urban areas—particularly in municipalities other than Nairobi and Mombassa.

While a visual inspection is useful to determine whether minimum wages might be altering the shape of the wage distribution, it does not provide conclusive evidence about the relationship of minimum wages and earnings controlling for individual characteristics and other factors that influence the wage level. We do so, by estimating the following specification separately for agricultural and general order:

$$\ln W_{ioj} = \mathbf{a} + \mathbf{b} \ln MW_{oj} + X_i \Gamma + \mathbf{t}_o + \mathbf{t}_j + \mathbf{t}_s + \mathbf{e}_{ioj} \quad (1)$$

where W_{ioj} is monthly real wage of worker i in occupation o and location j ; MW_{oj} is the monthly real minimum wage for occupation o and location j ; X_i is a vector of personal characteristics (level of education, gender and age); \mathbf{t}_o , \mathbf{t}_j and \mathbf{t}_s are sets of indicator variables for occupation, location and sector of employment (formal or informal), respectively and \mathbf{e}_{ioj} is the error term. In some specifications we also include interactions of the minimum wages with personal characteristics and the sector of employment.

The first and the fourth columns in Table 9 report the simple correlation between the level of wages and minimum wages, for agricultural and general order minimum wages. Such correlation is found to be positive and statistically significant for agricultural activities. A positive association however does not provide conclusive evidence that higher minimum wages are causing higher wages, since the reverse causality is also likely to be in effect: occupations with higher wages have associated higher minimum wages. To correct for this issue, columns (2) and (4) in Table 9 examine the correlation between wages and minimum wages controlling for a number of individual and job characteristics that explain the level of wages across occupations. Once these effects are taken into account, the minimum wage is no longer significant in explaining the level of wages for the average worker.

Yet, minimum wages may be relevant for explaining the wage level of workers of certain types, particularly those whose wages are more likely to be close to the minimum wage. To account for such possibility, we add interactions between the minimum wage level and individual characteristics of workers (age, gender, education level, and whether formal or informal). We report the results in columns (3) and (6) of Table 10. Given that minimum wages vary by occupation, in agriculture, the level effect of the minimum wage is absorbed by the inclusion of occupation effects. The coefficients on the interactions between the minimum wage and the personal characteristics indicate whether minimum wages affect some workers more than others. The only coefficient that is statistically significant is the interaction with age. The negative sign suggests that in agriculture, minimum wages exert a stronger upward push on wages for the adult population than for younger workers.

The level effect of the minimum wage can be recovered in urban areas because minimum wages vary by location within occupation. Its coefficient indicates that minimum wages exert an upward push on the wages of less educated workers. The results also indicate that minimum wages exert a higher push on the wages of women, thereby contributing to reduce the gender earnings gap.

VI. Minimum Wages and Employment

Evidence on the effect of minimum wages on employment in Kenya is scarce. To our knowledge, only one study studied this issue and concluded that minimum wages reduce employment (Omolo and Omitti, 2004). Their conclusions are based on an estimated negative correlation between changes in the minimum wage and changes in employment using aggregate data. As noted before however, a negative correlation does not establish causality. It could well be, for example, that the causality goes in the opposite direction, that is, periods of low employment growth, and in general poor output growth, lead to lower increases in the minimum wage.

Given the problems associated with using aggregate time series data, the economic literature relies on repeated cross sectional or longitudinal data at the individual level to estimate the effect of minimum wages on employment. Unfortunately, there is not much labor market micro data available in Kenya. To our knowledge, in the last 10 years there was only one labor force survey that covered urban areas. Nonetheless, the presence of a large number of minimum wages levels across occupations and locations provides important cross sectional variation that we can exploit with the 98/99 ILFS data to relate employment to the multiple minimum wages.

The existing data suggest that high minimum wages in urban areas lead to a reduction in formal salaried employment and an increase in the share of self-employed. Figure 8 relates the ratio of the minimum, for each occupation-location pair, to the median wage for all salaried workers with the share of formal salaried employment, the share of

informal salaried and the share of self-employment in total employment for each location-occupation pair. We restrict the analysis to urban areas since the wage analysis suggests that these are the areas where minimum wages are more likely to be binding.⁷ Total employment includes salaried, self-employment, unpaid work and apprentices. The number of data points in these figures is constrained by: (i) the number of occupation-location pairs for which a minimum wage is defined and (ii) the number of occupation location pairs for which a sufficiently large number of observations are available in the survey.⁸ This data suggest a negative relationship between the level of the minimum wage –in relation to the median—and the share of formal salaried employment. It also suggests a strong positive association between the share of self-employment and the minimum to median wage ratio. Notice, for example, that the correlation coefficient between the share of formal salaried employment and the minimum to median wage ratio is -0.46 while the correlation between the share of self-employment and the minimum wage in the cross section of occupations-locations is equal to 0.58. In contrast, the correlation with informal employment is very small and negative (-0.09) indicating that minimum wages may also reduce employment for salaried informal workers. We formalize these results by estimating the following regression:

$$S_{oj} = \mathbf{a} + \mathbf{b}_1 K_{oj} + \mathbf{e}_{oj} \quad (2)$$

Results are presented in tables 11 and 12. The dependent variable S_{oj} is the share of formal salaried (columns 1 and 4), informal salaried (columns 2 and 5), and self-employed workers (columns 3 and 6) in total employment. K_{oj} is the minimum to median wage ratio and \mathbf{e}_{oj} is the error term. The results on Table 11 are based on occupation-location-specific minimum to median wages while the results on Table 12 are based on the ratio of the occupation-location specific minimum wage to median wage for all salaried workers. The results on Table 11 indicate that, assuming a minimum cell size of

⁷ From the econometric point of view restricting the analysis to urban areas allow us to control for location and occupation fixed effects, which greatly reduces the possibility of omitted variable bias.

⁸ In figure 8, we do not consider occupation-location cells for which the number of observations available in the survey is below 35.

10 observations, a 10-percentage point increase in the minimum to median wage reduces the share of formal salaried employment by 4.1 points, while increasing the share of self employment by 4.7 points. These results are statistically significant at the five percent level for self-employment and at the 10 percent level for salaried employment. In contrast, minimum wages are found to have a marginal effect on informal salaried employment. The level of significance increases and the size of the coefficients becomes larger –but of similar magnitude-- if the threshold for the cell size is increased to 35 observations (columns 4-6).

Results become weaker if rather than measuring the level of the minimum wage with occupation-location-specific minimum to median wage ratios, they are instead measured with the ratio of each minimum wage to the median wage of all salaried workers.⁹ Using this methodologically better measure leads to much smaller estimates of the association between minimum wages and formal and self-employment. These estimates also suggest a decline in informal salaried employment as a result of higher minimum wages. Yet, given the number of observations, none of these coefficients are statistically significant at conventional levels.

However, increasing the threshold for cell size to at least 35 observations increases the size and significance of effects for formal employment and self-employment. The direction and size of the estimates is now in line with the ones summarized on table 11. A ten percent increase in the minimum to median ratio would lead to approximately 5.6 percentage points decline in the share of formal employment and a 5.9 percentage points increase in the share of self-employment. In sum, the evidence suggests that minimum wages in Kenya increase the share of self-employment and reduce the fraction of workers in formal, and possibly informal, salaried jobs.

⁹ The latter measure is better from a methodological point of view because it minimizes reverse causality. This arises from the fact a higher share of informal, or self employment in total employment may reduce the median wage, and therefore increase the minimum to median wage in a given occupation-location.

VII. Conclusions

This paper has reviewed the main arguments in favor and against minimum wages. While efficiency-wage arguments may be an important part of the story, the main reason for instituting minimum wages is not to fight poverty or inequality: there are other instruments to achieve that goal. Instead, the main justification is to empower workers whose wages are constrained by the excessive market power of employers. The most important argument for not fixing minimum floors is that this instrument can price many workers out of formal employment. Most of the evidence for developing countries points to negative employment effects.

The analysis developed in this paper, based on cross sectional data for 1998/99, indicates that minimum to median wage ratios were quite high, particularly for workers in more skilled occupations. At the same time, non-compliance affected one in four salaried workers in agriculture and one in six in urban areas. Non-compliance was higher for women, youth and workers with a low level of education attained.

Some possible causes for the low level of enforcement of minimum wages in Kenya are the following. First, the many different number of categories of minimum wages makes it very difficult for workers and firms to know them. Second, minimum wages are set at levels that are too high in relation to the median wage –especially for semiskilled and more skilled occupations-. Finally, the classification of occupations used for the minimum wage is outdated implying that many occupations may no longer be adequate for the requirements of today’s labor market.

The evidence indicates that minimum wages pushed up wages in the general order, but not in the agricultural industries. The indication would then be that relatively low minimum wages, combined with non-compliance, limited the effect of the minimum wage in that sector. Instead, there are signs that minimum wages in the general order raised wages for unskilled workers and women. However, there are also strong indications that such policy may have adverse effects on formal sector employment. Our

estimates indicate that a 10 percent points increase in the minimum to median wage ratio would be associated with a decline in the share of formal employment of between 1.1-5.5 percentage points –and an increase of between 2.7-5.9 points in the share of self-employment.

This paper has provided some initial steps towards an evidence-based diagnostic of the effectiveness of minimum wage policies. However, such analysis is hampered by the scarcity of labor market data. Up-to-date techniques to investigate the effect of minimum wages on poverty, inequality and employment require longitudinal micro data, or in its defect, a series of consecutive household level surveys taken with a quarterly, yearly or biannual frequency. Such data is not available in Kenya, where there are few and far apart household level surveys to rely upon. Improving the frequency of data collection to at least once labor force survey every two years would go a long way towards developing better labor market policies.

**Figure 1: Evolution of Minimum Wage
GDP per capita and Average Wage in Real Terms**

Source: Own calculations based on Economic Survey (Central Bureau of Statistics), various years. Minimum wages correspond to the values for Nairobi and Mombassa and for general laborers. Average wages are for the private sector and are obtained from the Economic Survey (various years) and were deflated with CPI from World Development Indicators, World Bank. Minimum Wages were deflated with a price index for the lower income group in Nairobi.

Figure 2: Ratio of Minimum to Average Minimum Wage

Source: Minimum wages correspond to the values for general laborers in Nairobi and Mombassa. Average wages are for private sector workers and are obtained from the Economic Survey (various years).

Figure 3: Minimum Wage level (relative to Median Wage for salaried population) and % of Non-Compliance by occupation-location pairs

Source: Authors elaboration from Labor Force data for period 1998/99. Each data point corresponds to the ratio of the minimum to the median wage and the non-compliance rates for one occupation-location pair (for example, unskilled workers in agricultural sector). For each occupation–location pair, the median wage is computed for overall salaried employment.

Notes: Fraction below is the percentage of workers paid below their corresponding statutory minimum. Fraction at +/- x% is the fraction of salaried workers that received monthly wages within a range of plus/minus two and five percent of the statutory minimum wage. Fraction affected is the proportion of people earning a real wage between the 1998 and the 1999 minimum wage. The minimum to median ratio (Median salaried) is also known as Kaitz Index.
