

Reconciling Motherhood and Work

Evidence from Time Use Data in Three Countries*

Abstract

Reconciling motherhood and work remains today a problem for many women, specially in Southern European countries. Inasmuch as parental care is good for children, the latter may suffer if mothers as well as fathers are employed.

In this paper we compare evidence based on time use data for three countries: Italy, Germany and Sweden. Although in each of them working mothers appear to dedicate less time to child care than non working mothers, Sweden is the country where the difference is smaller. In Italy, instead, maternal work is associated with the largest loss of maternal care for children.

We argue that while child care facilities increase mothers' access to employment, it is the availability of flexible working arrangements that allows them to work and still have enough time to allocate to child care. While this seems to happen in Sweden, although at the cost of a high degree of gender segregation by occupation, in Germany and Italy, where part-time jobs are scarce, mothers are forced to work full-time if they want to enter the labor market. This has a large negative impact on the time they can devote to their children independently of the availability of formal or informal child care facilities. In the light of these considerations, some policy implications are discussed.

Keywords: Time use, Child care, Labor market institutions.

1 Introduction

Since in most western economies, and specially in Southern European countries, fathers are typically reluctant to change their working habits and their attitudes towards family duties, men's share of total domestic labor is still far below that of women.¹ Therefore, reconciling motherhood and employment remains today a problem for many women. Given that a day cannot have more than 24 hours, going to work implies necessarily cutting on other activities and one which is at risk of significant reduction is child care.

Is there a negative effect of parental employment on children's outcomes? This question has been the object of an extensive empirical research with mixed results.² However, the most recent studies, probably based on higher quality data, seem to point more consistently towards the finding of worse children's outcomes associated with parental employment as far as educational achievements are concerned.³ Moreover, the assessment of negative consequences seems to extend also to other outcomes beyond cognitive development.⁴

Independently of these considerations, it seems plausible that parents are on average the best suited persons to take care of their children for at least a non-trivial part of the day. If this is true, it becomes important to measure the extent to which child care provided by mothers (and fathers) decreases when they work.

Despite how relevant this assessment is, given the trend of increasing female labor market

¹See UN (1995) and Del Boca and Locatelli (2003).

²As far as cognitive development is concerned the literature encompasses papers that highlight positive effects (Vandell and Ramanan, 1992; Parcel and Menagham, 1994) as well as papers that uncover negative consequences (Leibowitz, 1977; Stafford, 1987; Mott, 1991) but in most cases no systematic evidence is found (Desai et al., 1989; Baydar and Brooks-Gunn, 1991; Blau and Grossberg, 1992; Hanushek, 1992, Waldfogel et al., 2000; Neidell, 2000).

³Ruhm (2000), using data from multiple years of the National Longitudinal Survey of Youth (NLSY) and controlling for a large set of characteristics, finds that maternal employment during the early years of a child's life has a small negative effect on the verbal ability of 3 and 4 year old and a substantial detrimental impact on the reading and math achievement of 5 and 6 year old. Interestingly these negative consequences are more evident in traditional two-parent families and paternal employment is shown to be similarly detrimental for children. Ruhm's overall conclusion is that "previous research may have provided an overly optimistic assessment of the effects of parental employment on child cognitive development." This conclusion is confirmed by Francesconi and Ermisch (2000) using data from the British Household Panel Survey.

⁴Currie and Hotz (2001) use the NLSY and Vital Statistical records finding that the effects of maternal employment on unintentional injuries to children is positive for blacks and negative for whites in models that control for child-specific fixed effects, suggesting also that the effect of maternal employment may be mediated by child care regulations. Anderson et al. (2002) use again the NLSY to show that a child is more likely to be overweight if his/her mother worked more hours per week over the child's life, and the result is robust to the use of techniques aimed at evaluating the causal nature of this relationship, like sibling differences or instrumental variable models.

participation in the western world, it is striking that to the best of our knowledge only Hofferth (1999) addresses explicitly and directly this issue showing that in the US employed mothers spend less time on child care than their counterparts without jobs. Several less recent papers indirectly suggest the possibility of a more diversified relationship between parental work and time devoted to child care, depending on the role of the education level of mothers and fathers.⁵ In any case, no one seems to have addressed the question of which institutional setting makes it easier for mothers to work without reducing too much the time they can allocate to child care.

In this paper we try to fill in this gap by comparing evidence based on time use data for three countries: Italy, Germany and Sweden. Although in all these countries working mothers appear to spend less time on child care than non-working mothers, Sweden is clearly the country where the difference is smaller as well as statistically insignificant. To shed light on the possible reasons of this finding we consider the role of part-time job opportunities and formal or informal child care arrangements. These two factors are typically considered crucial to explain the extent to which females can reconcile motherhood and work in different countries.⁶ There is, however, an important and often neglected difference in the way in which these two factors facilitate a reconciliation. If formal child care arrangements are available in the absence of part-time employment opportunities, it is certainly easier for mothers to work but at the cost of a considerable reduction of the time they are able to spend on child care because only full-time jobs can be found. If instead flexible job opportunities are available in conjunction with child care arrangements, mothers can work without giving up completely the possibility to spend time on child care. Our evidence from time use data joint with information on the availability of part-time and child care arrangements suggests that the second of these two ways to reconcile motherhood and work characterizes Sweden, in contraposition to Germany and Italy where the first way seems to prevail. However, nothing comes without a cost. The Swedish solution favors the reconciliation of child care with maternal work, but since part-time jobs are easily available only in certain occupations and sectors, this solution entails a considerable amount of gender segregation by occupation, as for example shown by Breen and

⁵Hill and Stafford (1974, 1980) and Leibowitz (1974a, 1974b) show that highly educated mothers are more likely to work but at the same time tend to dedicate more time to children than low educated mothers. Gronau (1976), however, finds for Israel no difference in time dedicated by mothers to children across education levels.

⁶See, for example, Del Boca (2002).

Garcia-Pealosa (2002).

After a description of the data in Section 2, Section 3 presents and discusses our evidence, while Section 4 concludes.

2 The Data

Our analysis is based on three data sets constructed from time-budget studies for Italy (1989/90), Germany (1990/91) and Sweden (1984/85). These surveys contain information on labor market participation, education, family structure and general demographic characteristics. As for the time use information, Table 1 summarizes the essential features of the time diaries completed in the three countries. Each respondent was asked to complete a time diary on one day in the Italian survey and on two days in the German and the Swedish surveys. Our empirical work is based on diaries for weekdays (that is, from Monday to Friday) and for Sundays. Both the Italian and the German surveys obtain time use information from all the adult household members. Note, however, that the Swedish survey only provides time diaries for the husband and the wife and, in some cases, for a third person present in the household. As for the number of possible activities, individuals' responses are coded into 151, 230 and 72 separate categories in the Italian, German and Swedish diaries, respectively. The time units into which the days are disaggregated are 5 minutes long in the German time-budget, whereas the Italian and Swedish diaries do not present time slots and respondents must specify when each activity begins and finishes.

We use information on the number of minutes devoted to child care by the mother and by all the other household members excluding siblings younger than 15. In what follows, we focus on the number of minutes allocated to child care divided by the number of children under 15 present in each household.⁷ Unfortunately, it is not possible in any of the data sets used to identify the exact amount of time that household members devote to the care of each of the children.

Our data sets are detailed enough so that we can distinguish two main types of child care: quality and basic.⁸ Quality child care encompasses activities linked to children's educational

⁷Note, however that in the regressions used to predict time spent on child care, the number of children under 15 is also included as a control variable on the right hand side of each estimated equation. This is needed to allow for the possibility of economies (or diseconomies) of scale in child care.

⁸The sum of the minutes devoted to the two types of child care is by definition equal to the total amount of

and cultural development, while basic care encompasses activities related to children’s more essential needs. Table 1’s last two rows present the exhaustive list of activities that we have classified as quality and basic child care in the three countries. The distinction between quality and basic child care is quite homogeneous in Italy and Germany. However, we cannot make such a careful distinction for Sweden, where the range of possible child care activities encompasses only three categories: active child care (that we refer to as quality care), passive child care and care of a sick child (that we have classified as basic care).

The final samples for our analysis have been selected from the original samples on the basis of three criteria. First, households are excluded if the information needed to specify the relationship between all its members is not available.⁹ Second, since our goal is to explore the link between maternal employment and the amount and characteristics of the time allocated to child care, we keep only two-parent households with children under 15 years old.¹⁰ The third criterion requires the exclusion of all the households for which one or more of the variables used in the analysis are missing. These three criteria leave us with 1,292, 1,749 and 411 households for Italy, Germany and Sweden, respectively.

Table 2 presents summary statistics for the key variables used in the analysis for the three samples.¹¹ Mothers work in 76% of the households in the Swedish sample, against only 65% and 43% of the households in the German and Italian samples, respectively. The average number of children under the age of 15 in our samples is 1.45 in Italy, 1.84 in Germany and 1.70 in Sweden.

Regarding education, individuals have been classified as highly educated if they had access to college (even if they did not actually go to college) or had a higher qualification and as low educated otherwise. According to this classification, almost 30 percent of mothers are highly educated in the three countries. Note also that mothers are also slightly younger¹² and less minutes dedicated to child care

⁹The reason why we have not used the 1993 wave of the Swedish Household Market and Non Market Activities Survey, which also contains time use diaries, is that in this wave there is not enough information to correctly identify the role of all household members.

¹⁰Unfortunately, most time-budgets have small samples which in this case prevent us from performing a separate analysis for households with pre-school age children.

¹¹For Italy, we report summary statistics for the weekday sample. Statistics for the Sunday sample are of course identical given that both samples are extracted randomly from the original population.

¹²In the German data set, age is not reported as a continuous variable but as a categorical variable with five year intervals. We have imputed to each individual the median value of his/her interval.

educated than fathers in the three countries.

Finally, note that adult individuals different from the parents and from children older than 14 are present in 6% and 4% of the Italian and German households, respectively, while they are never present in our Swedish sample.

3 Maternal Employment and Child Care

3.1 The Effect on a Working Day

Table 3 presents evidence on the effect of maternal employment on child care in a working day. The first row reports the average number of minutes that working or non-working mothers devote to child care per child under 15. These statistics are adjusted predictions computed at sample averages after controlling for the following observable characteristics: mother's age, father's age, mother's and father's education dummies, number of children under 15, number of children over 14, number of grandparents, number of other adults and region dummies. Note, in particular, that the number of children under 15 is included on the right hand side of each estimated equation in order to allow for the possibility of economies (or diseconomies) of scale in childcare.

Germany is the country where non-working mothers spend more time on child care, with an average of 82 minutes per child on a daily basis from Monday to Friday. Perhaps unexpectedly with respect to some stereotypes,¹³ Italian non-working mothers come second in the ranking with 63 minutes per child. Much less time is instead devoted to child care by Swedish non-working mothers (40 minutes). However, this ranking is substantially modified when we look at the changes induced by maternal work. These changes are reported in percentage terms in the second row of each panel. The correspondent t-statistics for the null hypothesis of a zero change is given in parentheses. While Swedish working mothers dedicate 3% more time to child care than their non-working counterparts (but the difference is not statistically significant),¹⁴ the corresponding figure for Germany is -28% and Italy reaches the lowest level of -41%. In both Italy and Germany, these differences are statistically significant. As a result, Italy is the country where working mothers allocate less time to child care: 37 minutes against 41 in

¹³See "Mamma mia", *The Economist*, 1 April 2000.

¹⁴Since the Swedish sample has fewer observations, differences in significance across countries should be considered with caution.

Sweden and 60 in Germany (see the first row).

Although it is hard, if not impossible, to disentangle with the available data the combination of historical, cultural and institutional factors that determine these cross country differences, it has been argued that the availability of child care and part-time work¹⁵ are the two crucial factors that explain the extent to which females can reconcile motherhood and work in different countries.¹⁶ However, these two factors facilitate a reconciliation in very different ways. When formal child care arrangements are available but part-time employment opportunities are scarce, it is easy for mothers to work but this decision necessarily implies a considerable reduction of the time they can spend on child care because only full-time jobs are available. If instead a combination of part-time opportunities and child care facilities is available, mothers can work without giving up completely the possibility to spend time on child care. In what follows we investigate the possibility that a successful combination of part-time work opportunities and child care facilities is what allows Swedish mothers to work and still be able to spend a considerable amount of time on child care relative to their non-working counterparts.

Table 4 shows that in our Italian sample 56% percent of mothers do not work and among those who work, the majority works full-time. Only 19% of all Italian mothers have a part-time job and survey evidence shows that this is not the result of female preferences against shorter working hours. For example, the European Commission (1993 and 1995) shows that in Italy, and more generally in Europe, the majority of female employees would prefer to work less hours even if this implies a proportional reduction of labor income. Although in 1984 a reform eliminated the institutional constraints that penalized the diffusion of part-time jobs in Italy, these jobs are still infrequent, mainly because of the opposition of employers who fear the organizational costs of shorter working hours.¹⁷ Also trade unions, which otherwise favor a generalised compulsory reduction of working time, oppose the optional availability of part-time jobs on the ground that it may create “ghettos” of lower quality occupations. As a result of this widespread opposition from employers and employee organizations, the possibility for parents

¹⁵And, more generally, the availability of flexible time contracts, job sharing, or tele-working. Unfortunately, we do not have information on the diffusion of these types of working arrangements in the three countries we consider for the years in which we have time-use data. For this reason, in what follows we will only refer to part-time jobs, but our line of argument extends to all contractual arrangements that give flexibility to labor supply.

¹⁶See, for example, Del Boca (2002).

¹⁷See Del Boca (2002), Del Boca (1993) and P. Ichino (2003).

of reconciling work and child care through a flexible allocation of time between alternative activities is severely hampered in Italy.

Table 5 shows that, as far as child care services are concerned, the situation is slightly more favorable to female employment in Italy. According to OECD, only 6% of children under 3 years of age had access to these facilities in 1998. However, it should be noted that both male and female Italian workers can easily obtain a leave of absence during the first three years of life of a child, and in some sectors these leaves of absence are even partially compensated. Moreover, 95% of children older than 3 have access to the formal school system which takes care of them for a large part of the day until the end of elementary school. More precisely, for children younger than 10, schools are typically open from 8.30 in the morning until 16.30 in the afternoon, with the possibility of extensions for working parents. The situation of children older than 10, but still in mandatory school age, is more problematic because junior high school lasts only until 13.00 approximately, although for six days per week. This is evidently a problem for families with working parents, if part-time jobs are not available. In these cases the solution is often offered by extended family networks, which are an aspect of the Italian situation that we explore below.

As a result, Italy appears to be characterized by some relatively accessible kinds of formal or informal child care arrangements, matched by a very limited access to part-time jobs. Therefore, it is not surprising to observe in our data that very few Italian mothers work (Table 4) and at the same time those who work are forced to reduce substantially the time they can allocate to child care (Table 3).

At the opposite extreme is the Swedish situation, where formal child care facilities and part-time opportunities are well known to be quite accessible. As many as 77% of the mothers in our Swedish sample work (and the data are for 1984!), and, more importantly, the bulk of the difference with respect to Italy is generated by part-time workers (46% in Sweden against only 19% in Italy). The difference in full-time work is actually quite small (30% in Sweden against 23% in Italy). Regarding child care services, Table 5 shows that, in 1998, 48% of children under 3 years of age were in formal child care, and the same was happening to 80% of the older children. We do not have similar data for 1984, the year of our Swedish time use survey, but they are probably not very different given that, in that year, we observe that most Swedish

mothers work without having to reduce by a large amount the time spent on child care (Table 3).

Germany takes an intermediate position in terms of female employment in both full and part-time jobs, with child care services similar to the Italian ones. Nevertheless, in terms of consequences of maternal work for the time mothers can spend with children, Table 3 shows that Germany is much more similar to Italy than to Sweden.

In light of the evidence so far presented, it is fairly clear that maternal employment reduces the time mothers can dedicate to child care in the three countries. However, the Swedish experience strongly suggests the possibility that institutional arrangements can substantially limit this undesirable consequence of female labor market participation. This is clear from the observation of Table 6, which reports the amount of time spent on child care by the mother according to whether she works full-time, part-time, or does not work.¹⁸ In all countries, mothers working part-time dedicate more time to children than mothers working full-time and in Sweden there is actually no difference between the time dedicated to child care by mothers who work part-time and mothers who do not work.

However, nothing comes without costs. A wide literature¹⁹ has shown that Sweden is characterized by the highest degree of gender segregation by occupation among OECD economies. This is likely to be the consequence of the fact that part-time jobs are easily available in certain occupations and sectors while being rare in others. If females mainly work in part-time jobs, the finding of gender segregation by occupation cannot come as a surprise. As a result, while the Swedish solution favors the reconciliation of child care with maternal work, it also entails the possibly undesirable consequence of increasing gender segregation by occupation.

3.2 Quality care and basic care

As explained in detail in Section 2, an interesting aspect of the time use data at our disposal is the availability of information which allows us to distinguish between quality child care and basic child care. A further important aspect of the Swedish success in comparison with Italy and Germany is offered by the fact that in these two latter countries it is the quality type of care the one most reduced when mothers work. The second panel of Table 3 shows that quality care

¹⁸We thank Anders Klevmarken for suggesting the inclusion of this table in the paper.

¹⁹See for example Breen and Garcia-Pealosa (2002), in particular Table 1.

is reduced by 49% and 40% when the mother works in Italy and Germany, respectively, while in Sweden it actually increases by 3%, albeit in a statistically insignificant way. Moreover, in the first two countries the reduction of basic care is substantially smaller than the reduction of quality care (37% in Italy and 24% in Germany) while in Sweden differences of effects between types of care are smaller.

It is obviously impossible to attribute these differences to a well defined set of causes, but it seems reasonable to believe that the time dedicated to basic care can be compressed less than the time dedicated to quality care. This might be the reason why Italian and German mothers have to cut on quality child care more than Swedish mothers, given that the former are more likely to work full-time if they work. In other words, basic forms of child care, like feeding the children, must take priority in the limited amount of time Italian and German mothers have at their disposal after working full-time. The evidence presented suggests that basic child care takes precedence over quality forms of child care, like reading and playing with children.

The figures for Sweden should be considered with some caution because, as discussed in Section 2, they are not directly comparable to the figures in the other two countries. Sticking to the Swedish definition of quality care, it seems nevertheless reasonable to say that if a Swedish mother spends time on child care, she does so mostly in activities that imply an active form of care, as if more passive types of care could be left to public institutions.

3.3 The contribution of other household members

As we already mentioned, a specific aspect of the Italian model of reconciliation of motherhood and work is the role of other members of the household. In addition to the father, these are primarily grandparents, aunts and uncles. Also adult children are frequently living at home in Italy (see for example Bentolila and Ichino (2003) and Becker et al. (2002)). However, in Ichino and Sanz de Galdeano (2002) we show that the amount of time devoted to child care by adult children living in the household is negligible. Hence, in what follows, with the words “other adults” we refer to any adult in the household different from parents and adult children (that is, children older than 14).

Table 7 shows that in Italy the probability that other adult members are present in the household is higher than in Germany. More importantly, from the viewpoint of this paper, this

probability more than doubles when the mother works as opposed to when she does not work (9% against 4%). A smaller difference is observed for Germany (5% against 3%), where the presence of other adults is in general less likely than in Italy. On the contrary in our Swedish sample, independently of maternal work, there are no households with other adults present in addition to parents and adult children, which explains the empty cells for the Scandinavian country in Table 7.

It is impossible with the available data to determine the direction of causality between maternal work and presence of other adult members. It could be that the mother can go to work because, for example, the grandparents live in the household, or it could be that the latter are invited to join the household because the mother wants to work. In any case, it is clear that other adult household members are likely to play an important role in the Italian way to reconcile motherhood and employment.

Table 8 shows that our time use data confirm this conclusion. This table reports figures on the time dedicated to child care by other adults in the restricted samples of households in which other adults are present. Since with this restriction we have no observations for Sweden, the cells of Table 8 are empty for the Scandinavian country as in Table 7.

Italy is the only country where the amount of time in which children are taken care of by other adults in the household increases when the mother works and the difference is statistically significant at the 10% level. When the mother does not work, other adults dedicate relatively little time to child care (8 minutes per day), but when the mother works this time increases to 19 minutes which correspond to 51% of the time the working mother dedicates to each child every day. In Germany instead there is basically no difference in the role of other adults as a function of whether the mother works or not.

As far as the distinction between quality and basic care is concerned, other interesting differences emerge between Italy and Germany. In Germany, other adults approximately devote the same amount of time to quality and basic care when the mother works and when she does not. In Italy instead when the mother works basic care is the type of care to which other adults give the greatest contribution.

This suggests again, as observed in Section 3.2, that the time allocated to basic care is more difficult to compress. If parents cannot offer a sufficient amount of this type of care, someone

else has to do it, and in Italy this role appears to be taken by other adults in the household when they are present.

Since in Italy other adults spend more time on basic care than on quality care when the mother works, this latter is the type of care which seems to suffer the most in case of maternal work. Interestingly, fathers, who are basically all working in our samples, compensate slightly for this effect, as shown in Table 9. When the mother does not work, two thirds of paternal time dedicated to children in Italy takes the form of quality care, and this figure increases by 46% when the mother works. As a result, considering the corresponding figures for mothers from Table 3, when the mother and the father work they approximately dedicate the same amount of time (11-12 minutes per child and per day) to quality child care. The mother is instead relatively more involved in basic care.

A different pattern prevails in the other two countries. In none of them fathers change behaviour significantly when the mother works, but while in Germany they are relatively more involved in basic child care, in Sweden all of their time is devoted to quality care. All in all, the evidence suggests that, even in Italy, fathers do not come close to compensate the loss of child care implied by the working decision of the mother, which leaves open the problem of what parents can do to ensure that children are taken care of when they work.

There seems to be no evident reason to argue that other relatives are a preferable second best solution in comparison to public or private child care arrangements when both parents work. But independently of whether relatives are better than formal facilities, the Italian solution does not seem to help in allowing the mother to limit the loss of child care she can provide to her children when she decides to work. The reason is that even if the solution based on relatives provides greater flexibility, when part-time jobs are not available it does not really matter whether relatives or the school system take care of children, from the viewpoint of increasing the time that working mothers can spend with them. It is not the flexibility of child care that matters: what matters is the flexibility of jobs.

3.4 The Effect on a Sunday

Table 10 replicates Table 3 using Sunday diaries instead of working day diaries. There is no evidence in any of the three countries that holidays are used on average by working mothers to

make up for the time that they cannot spend on child care from Monday to Friday. In Sweden, we even observe an almost statistically significant decline in maternal child care on Sunday when the mother works.

Interestingly, in the Scandinavian country this decline appears to be associated with a large amount of time dedicated to leisure, which amounts to 33% of total Sunday time for Swedish working mothers as opposed to 25% in Germany and Italy. In Italy, instead, housework takes a larger portion (20%) of Sunday time of working mothers in comparison to what happens in Sweden and Germany (15%).

3.5 Does the Effect Differ across Educational Levels?

When a parent decides to work he or she has obviously less time for leisure, housework and child care but the effect of the working decision on the time dedicated to each of these alternative activities does not have to be the same. Specifically, it is possible that the time for work is found at the expenses of leisure and housework with no or even a positive effect on the time spent on child care. This could happen in particular if, for example, parents can buy housework on the market thanks to the higher income they earn by working more hours. Whether this happens or not depends of course on preferences with respect to work on the market, housework, leisure and child care. If preferences for child care change significantly across education levels, also the effect of working decisions on time spent with children may change along the same dimension.

In the light of the evidence presented by Hill and Stafford (1974,1980) and Leibowitz (1974a, 1974b), one might expect that if educated mothers dedicate on average more time to child care, the effect of the decision to work on the time they dedicate to child care should be smaller for them. We explore this issue in Tables 11 and 12.

In the left part of Table 11, we look at highly educated mothers in a working day. Once again, the differences between the Swedish model and the Italian and the German models are striking. In terms of total and quality care these figures suggest that in the Scandinavian country highly educated mothers increase the time dedicated to children when they decide to work, although the difference with respect to non-working mothers is not statistically significant. On the contrary in Germany, and even more so in Italy, maternal work decreases substantially the amount of child care provided by mothers and the loss is statistically significant. In line

with our previous findings concerning the distinction between the two types of child care, the loss is stronger for quality care (47% and 40% in Italy and Germany, respectively) than for basic care (39% and 24%).

In contrast with the expectation based on the results of Hill and Stafford (1974, 1980) and Leibowitz (1974a, 1974b), the last three columns of Table 11 show that the picture is very similar for Italian households in which the mother has low education. Also in Sweden, low educated mothers devote less time to child care when they work, although this effect is not statistically significant. In Germany, the working decision of low educated mothers reduces (increases) the amount of time dedicated to quality (basic) care. However, none of these effects is statistically significant. Overall, the main difference with respect to highly educated mothers is that for all countries the loss of maternal child care time is more pronounced in the case of quality care. This result is in line with Gronau and Hamermesh (2003), who show that additional education (and thus income) does not alter the relative goods intensity of child care and that more educated parents do not substitute money for time as far as child care is concerned.

At least for Italy, this picture changes considerably on Sundays, as shown in Table 12. In Italy, this is the only day of the week in which the education level of the mother interacts significantly with the working decision in shaping the effect on the time dedicated to child care. In an average Italian household with a highly educated mother, she dedicates more time to child care on Sundays if she works than if she does not work. Most of this positive effect is generated by an increase in basic care, while the increase in quality care, although substantial in size, is statistically insignificant. A completely opposite pattern is instead observed on Sunday for low educated Italian mothers who appear to dedicate substantially less time to child care on holidays if they work.

No statistically significant pattern seems instead to emerge for the other two countries, although in contrast with Italy we observe some negative signs. In particular for Sweden, as already observed in Table 10, holidays do not seem to be used by working mother to spend more time on child care, independently of education.

Although we have no obvious explanation for this finding, Italy appears to be the only country where highly educated mothers who work try to compensate on Sunday the time they

do not devote to child care during the rest of the week. But even in these households, the loss of child care over the entire week remains substantial. An even larger loss prevails in households with low educated mothers.

4 Conclusion

In this paper we compare evidence based on time use data for three countries: Italy, Germany and Sweden. While in all these countries working mothers appear to dedicate less time to child care than non-working mothers, Sweden is clearly the country in which the difference is smaller in absolute terms as well as statistically insignificant. Italy is instead the country where maternal work is associated with the largest loss of maternal child care.

Inasmuch as parents are the most suitable persons to take care of their children for at least some time during the day, it seems important to understand why Sweden appears to be characterized by a more satisfactory model of reconciliation of motherhood and work.

We argue that the Swedish outcome is the result of the availability of flexible job opportunities more than of formal child care facilities. These facilities increase the access to employment for mothers, but do not help them to work and still be able to spend enough time with their children. In Germany and even more so in Italy, flexible job opportunities are scarce and therefore mothers are forced to work full-time if they enter the labor market. This has a large negative impact on the time mothers can spend on child care independently of the availability of child care arrangement offered by public services or extended family networks.

However, Sweden is also the country where we observe the largest degree of gender segregation by occupation and this is likely to be a consequence of the fact that females mainly work in part time jobs, often of lower quality, which are concentrated in certain specific occupation and sectors. Therefore, not even the “Swedish solution” is exempt from drawbacks.

In 1996 the “Rocard recommendation” of the European Parliament, invited the governments of the Union to reform the discipline of social contributions for part time work with the goal of creating incentives for the diffusion of this type of labor contract.²⁰ What motivated the recommendation was not the idea that working hour reductions could increase employment, but the observation that many European workers, in particular females, expressed clear preferences

²⁰See Rocard (1996) and Ichino P. (2003) par. 307, vol II, 350-351.

for a shorter working hours even at the cost of proportional wage cuts.²¹ In the light of the evidence presented in this paper, the Rocard recommendation was going in the right direction, but it was disregarded in most countries. As any other attempt to reduce working hours, it encountered the opposition of employers who typically fear the organizational costs of these initiatives. It also encountered the opposition of unions and feminist movements which favor compulsory reductions of working hours, but at the same time oppose discretion in working times because it may create “ghettos” of lower quality jobs, and the Swedish experience confirms the validity of this fear.

As argued on a theoretical basis by Aghion and Hermalin (1990), this is one of those cases in which “legal restrictions on private contracts may enhance efficiency”. They consider the case of maternity leaves and show that if they are not compulsory, females signing contracts which allow for such leaves signal their willingness to have children and therefore signal a lower expected productivity from the viewpoint of the firm. As a result, a separating equilibrium would emerge, with a less than optimal fraction of females on contracts with maternity leaves. In the case of preferences for working times and flexible working arrangements, the signaling implications are very similar, suggesting that only a compulsory working hour reduction for both genders would allow for a reconciliation between parental work and child care, causing less segregation of females in lower quality jobs.

Perhaps unfortunately, such an extreme policy implication is unlikely to have a chance of being seriously considered even in Europe. Nevertheless, our paper suggests that the possibility offered by part-time jobs to reconcile work and child care for parents, should tilt again the balance in favor of a reconsideration of the softer suggestions of the Rocard recommendation.

²¹See European Commission (1995).

Father's education: Low	0.68 (0.46)	0.67 (0.47)	0.63 (0.48)
N. Obs.	1,292	1,749	411

Note: Statistics based on the samples of households for which complete information is available on all the variables used in the statistical analyses. Standard deviations are reported in parentheses.

Table 3: Maternal Employment and Time Devoted to Child Care by the mother - Working day

Child Care Type	Italy		Germany		Sweden	
	No	Yes	No	Yes	No	Yes
Total	63	37	82	60	40	41
	(2)	(2)	(2)	(2)	(6)	(3)
	-41%		-28%		3%	
	(-7.76)		(-7.55)		(0.16)	
Quality	22	11	21	13	38	37
	(2)	(1)	(1)	(1)	(6)	(3)
	-49%		-40%		3%	
	(-5.31)		(-6.13)		(0.17)	
Basic	41	26	61	47	1	1
	(2)	(1)	(2)	(1)	(1)	(0.4)
	-37%		-24%		-0.5%	
	(-6.25)		(-5.96)		(-0.01)	

Note: The first row of each panel presents, for a working day, adjusted predictions of the amount of minutes allocated to child care per child under 15 in the household by the mother when she works and when she does not work. Standard errors are reported in parentheses. Adjusted predictions are calculated at sample averages using the coefficients from OLS regressions of the corresponding dependent variables on a constant, mother's age, father's age, mother's and father's education dummies, n. children under 15, n. children over 14, mean age of children, n. grandparents, n. other adults and region dummies. The second row of each panel displays the percentage variation in the amount of minutes devoted to child care per child under 14 when the mother works. t-statistics from the underlying coefficients are reported in parentheses.

Table 4: Proportion of mothers in full-time work, part-time work and no work

Variable	Italy	Germany	Sweden
Full-time	0.23 (0.42)	0.28 (0.45)	0.30 (0.46)
Part-time	0.19 (0.39)	0.36 (0.48)	0.46 (0.49)
Not working	0.56 (0.49)	0.34 (0.47)	0.23 (0.42)

Note: Full-time work (part-time work) means more (less) than 6 hours per day. Standard deviations are reported in parentheses.

Table 5: Proportion of children in formal child care arrangements

Variable	Italy	Germany	Sweden
Age under 3	6	10	48
Age 3 to mandatory school age	95	78	80

Note: Percent of children in formal child school arrangements in 1998 (Italy, and Sweden) and in 2000 (Germany) as reported by OECD, Employment Outlook 2001, Adema (2001) and Del Boca (2002)

Table 6: Maternal child care and working hours

	Child Care Type	Mother does not work	Mother works part-time	Mother works full-time
Italy	Total	63 (73)	48 (55)	32 (38)
	Quality	22 (39)	16 (30)	10 (21)
	Basic	41 (54)	32 (41)	22 (28)
Germany	Total	82 (69)	66 (61)	53 (68)
	Quality	21 (30)	14 (26)	11 (21)
	Basic	61 (53)	51 (49)	42 (57)
Sweden	Total	42 (55)	42 (57)	38 (55)
	Quality	41 (54)	42 (57)	35 (54)
	Basic	1 (10)	1 (5)	3 (13)

Note: This table reports the amount of time the mother spends on child care per child when she works full-time, part-time and when she does not work.

Table 7: Presence of Other Adults and Maternal Employment

		Italy	Germany	Sweden
Working Mother	No	0.04 (0.001) *	0.03 (0.0005) *	-
	Yes	0.09 (0.001)	0.05 (0.0008)	-

Note: This table displays predictions of the probability that other adults are present in the household. Other adults are defined as any adult in the household different from parents and adult children. Adjusted predictions are calculated using the coefficients from probit models including a constant, working mother dummy, mother's age, father's age, mother's and father's education dummies, n. children under 15, n. children over 14, mean age of children and region dummies. Bootstrapped standard errors are reported in parenthesis. * indicates that the estimated coefficients on the working mother dummy are statistically significant at the 5% level, respectively.

Table 8: Maternal Employment and Time Devoted to Child Care by Other Adult Household Members - Working day

Child Care Type	Italy		Germany		Sweden	
	Is the mother working?					
	No	Yes	No	Yes	No	Yes
Total	8	19	19	19	-	-
	(4)	(6)	(7)	(5)		
	141%		0.6%		-	
	(1.79)		(0.01)			
Quality	5	6	7	7	-	-
	(3)	(3)	(4)	(3)		
	23%		2%		-	
	(0.36)		(0.03)			
Basic	3	13	13	12	-	-
	(2)	(5)	(5)	(2)		
	330%		-4%		-	
	(2.14)		(-0.09)			

Note: Other adults are defined as any adult in the household different from parents and adult children. The estimations is restricted to the samples of households in which other adults are present. Therefore, differently than in the other tables, the sample sizes are now 68 for Germany and 86 for Italy. The first row of each panel presents, for a working day, adjusted predictions of the amount of minutes allocated to child care per child under 15 in the household when the mother works and when she does not work by the other household members. Standard errors are reported in parentheses. Adjusted predictions are calculated at sample averages using the coefficients from OLS regressions of the corresponding dependent variables on a constant, mother's age, father's age, mother's and father's education dummies, n. children under 15, n. children over 14, mean age of children, n. grandparents, n. other adults and region dummies. The second row of each panel displays the percentage variation in the amount of minutes devoted to child care per child under 14 when the mother works. t-statistics from the underlying coefficients are reported in parentheses.

Table 9: Maternal Employment and Time Devoted to Child Care by the Father - Working day

Child Care Type	Italy		Germany		Sweden	
	No	Yes	No	Yes	No	Yes
Total	13	20	21	21	13	19
	(1)	(2)	(1)	(0.8)	(3)	(2)
	56%		3%		44%	
	(3.47)		(0.50)		(1.50)	
Quality	9	12	7	7	13	18
	(1)	(1)	(0.7)	(0.4)	(3)	(2)
	46%		-6%		37%	
	(2.36)		(-0.52)		(1.28)	
Basic	4	7	14	15	0.1	0.7
	(0.5)	(0.8)	(0.7)	(0.6)	(0.2)	(0.3)
	78%		8%		479%	
	(3.54)		(1.19)		(1.82)	

Note: The first row of each panel presents, for a working day, adjusted predictions of the amount of minutes allocated to child care per child under 15 in the household when the mother works and when she does not work by the father. Standard errors are reported in parentheses. Adjusted predictions are calculated at sample averages using the coefficients from OLS regressions of the corresponding dependent variables on a constant, mother's age, father's age, mother's and father's education dummies, n. children under 15, n. children over 14, mean age of children, n. grandparents, n. other adults and region dummies. The second row of each panel displays the percentage variation in the amount of minutes devoted to child care per child under 14 when the mother works. t-statistics from the underlying coefficients are reported in parentheses.
